

# MY-BASIC Quick Reference

## 1. Introduction

MY-BASIC is a lightweight cross-platform easy extendable BASIC interpreter written in pure C with less than twenty thousand lines of source code. MY-BASIC is a dynamic typed programming language. It supports structured grammar, and implements a style of OOP called prototype-based programming paradigm, furthermore it offers a functional programming ability with Lambda abstraction. It is aimed to be either an embeddable scripting language or a standalone interpreter. The core is pretty light; all in a C source file and an associated header file; simpleness of source file layout and tightness dependency make it feels extraordinarily tough. Anyone even C programming newbies could learn how to add new scripting interfaces in five minutes. It's able to easily combine MY-BASIC with an existing project in C, C++, Java, Objective-C, Swift, C# and many other languages. Scripting driven can make your projects more powerful, elegant and neat. It's also able to learn how to build an interpreter from scratch with MY-BASIC, or build your own dialect easily based on it.

This manual is a quick reference on how to program with MY-BASIC, what it can do and what cannot, how to use it and extend it as a scripting programming language.

For the latest revision or information, see [https://github.com/paladin-t/my\\_basic](https://github.com/paladin-t/my_basic); or contact with the author through <mailto:hellotony521@qq.com> to get support.

## 2. Programming with BASIC

The well-known programming language BASIC is an acronym for Beginner's All-purpose Symbolic Instruction Code; when we mention BASIC today, we often refer to the BASIC family, not a specific one. The BASIC family has a long history since an original BASIC was designed in 1964 by John George Kemeny and Thomas Eugene Kurtz at Dartmouth College in New Hampshire; and BASIC is famous because it is easy to learn and use all the time. Thank you all BASIC dedicators and fanatics.

MY-BASIC has a structured BASIC like grammar. It would be familiar to you if you ever had programmed with another BASIC dialect.

### Getting started

You can download the latest MY-BASIC package from [https://github.com/paladin-t/my\\_basic/archive/master.zip](https://github.com/paladin-t/my_basic/archive/master.zip) or check out the source use *git clone https://github.com/paladin-t/my\_basic.git* first if you didn't have a standalone interpreter yet. It is recommended to get a latest MY-BASIC package and have a quick blast with it first.

In this part let's get start using the MY-BASIC command line

interpreter, which comes as below:

The close square bracket is an input prompt. Let's begin rock it by typing a classical "hello world" tutorial as below:

```
' Hello world tutorial  
a$ = "Hello "  
a$ = a$ + "World"  
print a$
```

Like other BASIC dialects, MY-BASIC is case-insensitive; it means *PRINT A\$* or *Print a\$* will perform the same behaviour. You would get the response text after giving it a *RUN* command and hinting the enter key. Any text begins with a single quote and end to that line wouldn't be parsed to interpretable structure because it is a comment which won't influence the logic; a comment does not perform anything, it's just a short explanation of statements.

### Multi-line comment

MY-BASIC also supports multi-line comment surrounded by "*[*" and "*]*", for example:

```
print "Begin";  
[  
These lines won't be executed!  
print "Ignored";  
]  
print "End";
```

MY-BASIC will ignore these comments in this code.

### Support for Unicode

Unicode is widely used nowadays for international text representation; MY-BASIC supports both Unicode code identifier and string manipulation. For instance:

```
print "你好" + "世界";  
  
日本語 = "こんにちは"  
print 日本語, ", ", len(日本語);
```

### Keywords

There are a few keywords and some reserved function words in MY-BASIC as below:

Keywords	NIL, MOD, AND, OR, NOT, IS, LET, DIM, IF, THEN, ELSEIF, ELSE, ENDIF, FOR, IN, TO, STEP, NEXT, WHILE, WEND, DO, UNTIL,
----------	-----------------------------------------------------------------------------------------------------------------------

		EXIT, GOTO, GOSUB, RETURN, CALL, DEF, ENDDEF, CLASS, ENDCLASS, ME, NEW, VAR, REFLECT, LAMBDA, MEM, TYPE, IMPORT, END
Reserved words	Standard library	ABS, SGN, SQR, FLOOR, CEIL, FIX, ROUND, SRND, RND, SIN, COS, TAN, ASIN, ACOS, ATAN, EXP, LOG, ASC, CHR, LEFT, LEN, MID, RIGHT, STR, VAL, PRINT, INPUT
	Collection library	LIST, DICT, PUSH, POP, PEEK, INSERT, SORT, EXIST, INDEX_OF, GET, SET, REMOVE, CLEAR, CLONE, TO_ARRAY, ITERATOR, MOVE_NEXT

It is not allowed to use these words for user-defined identifier; in addition there are two more **TRUE** and **FALSE** predefined symbols besides these words, which represent Boolean value true and false, it's able to re-define these two symbols but it's not recommended. Meaning of each keyword will be mentioned latter in this manual.

## Operators

There are eleven operators in MY-BASIC as below:

Operators	+, -, *, /, ^, =, <, >, <=, >=, <>
-----------	------------------------------------

All these operators could perform in calculation or comparison. Besides these operators, keywords **MOD**, **AND**, **OR**, **NOT**, **IS** are operators as well. An operator priority level shown in the table below indicates execution order in an expression:

Level	Operation
1	- (negative), NOT
2	^
3	*, /, MOD
4	+, - (minus)
5	<, >, <=, >=, <>, = (equal comparison)
6	AND, OR, IS
7	= (assignment)

The priority of level 1 is the highest and level 7 is the lowest. Higher level operations are treated before the lower ones. An expression is processed from left to right; operations in a same level are dealt in the same direction. Brackets "(" and ")" are used in pair to tell the interpreter to process expression between them before operations outer.

*MOD* means modulus; it is usually signified by percent symbol "%" in some other programming languages. The caret symbol stands for power operation thus  $2^3$  results 8.

## Data and operation

A variable doesn't have a type, but a value does, so I could claim MY-BASIC is a dynamic type language. It's helpful to write code properly after learning some details about data types in MY-BASIC, although you could just assign whatever you want to a variable without taking care about data types most of the time. There are some kinds of built-in data types in MY-BASIC: Nil, Type, Integer, Real,

Boolean, String, Array, List, List Iterator, Dictionary, Dictionary Iterator, Prototype (aka. Class), and Sub Routine (including Lambda). Besides, MY-BASIC also supports user defined data types (Usertype and Referenced Usertype) to let you to customize your own data structures, it will be explained later.

Nil is a special type which includes only one value: *NIL*. A *NIL* represents nothing, similar to *null*, *none*, *nothing*, etc. in other programming languages. Assigning a variable with a Nil value will release/unreference the previous value it holds.

A Type typed value represents the type of a value, it will be explained later with the *TYPE* statement.

Integer and Real are defined as *int* and *float* in C types which are 32bit size under most compiler architectures nowadays. And you could redefine them with other types like *long* and *double* by modifying a few lines of code according to your requirement. The only instances of Boolean are *TRUE* and *FALSE*, and can be assigned from a Boolean expression or an Integer expression. Actually Boolean is implemented and treated the same way as Integer; zero means *FALSE* and non-zero means *TRUE*.

*NIL*, *FALSE*, and *0* all mean false in a Boolean expression; on the other hand all other value including a blank String "" mean true.

MY-BASIC accepts numbers in HEX and OCT representation. A hexadecimal number begins with a *0x* prefix, and an octadic one begins with a *0*. For instance *0x10* (HEX) equals to *020* (OCT) equals to *16* (DEC).

A variable identifier is formed with alphabet, underline and numbers, but it must begin with a letter or an underline. A variable does not require declaration before using, so pay attention to spelling mistakes to avoid unexpected behaviours. You don't need to take care of conversion between Integer/Float values, an Integer variable can be converted to a Float automatically if it's assigned with a Float value, and a Float value will be converted to an Integer if it doesn't has a real component. Notice that a String variable doesn't have to end with a dollar character \$, which maybe a little different from some early BASIC dialects. An assignment statement consists of a beginning keyword *LET* and a following assignment expression, practically the word *LET* is optional. See below:

*let a = 1 ' Assignment statement begins with LET*

*pi = 3.14 ' Another assignment statement without LET*

MY-BASIC supports array up to four dimensions by default (defined by a macro), without doubt you can redefine this limitation. Array is a kind of regular collection data structure in programming aspect. An array can store a set of data that each element can be accessed via the array name and subscript. A MY-BASIC array can hold either Real or String data; furthermore, it's able to store each type of data in an array by modifying a macro. An array must be declared by a *DIM* (short for dimension) statement before using like this:

```
dim nums(10)
dim str$(2, 5)
```

The naming rule for array identifiers is the same as variable naming rule. A dimension definition field followed an array identifier begins with an open bracket and ends with a close bracket. Dimensions are separated by commas. Array indexes begin from zero in MY-BASIC therefore *nums(0)* is the first element of array *nums*, note for this difference from other BASICs, but it's more common in most modern programming languages. An array index could be a non-negative Integer value formed as a constant, a variable of Integer or an expression which evaluation results an Integer; an invalid index would cause an out of bound error.

MY-BASIC allows you to concatenate two Strings together using operator plus “+” and get a concatenated String. So be aware of that each String concatenating operation would generate a new String object with memory allocation. Comparison operators can also apply to Strings. These operators start comparing the first character of each String, if they are equal to each other, it continues looking at the following ones until a difference or a terminating null-character “\0” is reached; then return Integer values indicating the relationship between the Strings: a zero value if both Strings are equal, a positive value if the first is greater than the second one, a negative value if the first is less than the second one.

## Structured sub routine

It is recommended to break a program into small sub routines. Sub routines can reduce duplicate and complicity code. MY-BASIC supports both structured sub routine with **CALL/DEF/ENDDEF** and instructional sub routine with **GOSUB/RETURN**, but you cannot use them both in one program. It's recommended to use structured **CALL/DEF/ENDDEF** to write more elegant programs.

A sub routine begins with a **DEF** statement and ends with **ENDDEF**, you can add any numbers of parameters to a sub routine. It's quite similar to call a sub routine with calling a scripting interface, note you need to write an explicit **CALL** statement, if you were calling a sub routine which was defined after the calling statement. A sub routine returns the value of the last expression back to its caller, or you may use an explicit **RETURN** statement. See below for example:

```
a = 1
b = 0
def fun(d)
    d = call bar(d)
sin(10)
    return d ' Try comment this line
enddef
def foo(b)
    a = 2
    return a + b
enddef
def bar(c)
    return foo(c)
enddef
r = fun(2 * 5)
print r; a; b; c;
```

As you may see, a variable defined in a sub routine is only visible inside the local routine scope.

MY-BASIC supports recursive sub routines and tail recursion optimization.

Besides, the **CALL** statement is used to get a routine value itself as:

*routine = call(fun) ' Get a routine value.*  
*routine() ' Invoke a routine value.*

Be aware it requires a pair of brackets.

### Instructional sub routine

Whatever, instructional sub routine is a valid option as well. A label is used to define the entry point of an instructional sub routine. You can use a **GOSUB** statement wherever in the program to call a labeled sub routine and transfer control to it. A **RETURN** statement is used to exit a sub routine and transfer control back to its caller.

### Control structures

There are three kinds of control structure in common structured programming languages; MY-BASIC supports them as well.

Serial structure that executes statements one by one is the most fundamental structure. MY-BASIC supports **GOTO** statement that provides unconditional control transfer ability. You can execute it like **GOSUB** as **GOTO label**, note instructional sub routine control proprietary cannot be returned back from a callee but unconditional **GOTO** cannot. Also, you cannot use both structured sub routine and unconditional jumping in one program. An **END** statement can be placed anywhere in source code to terminate the whole execution of a program.

Conditional structure consists of some condition jump statements

(such as *IF*, *THEN*, *ELSEIF*, *ELSE*, *ENDIF*). These statements check condition expressions then perform an action in a case of true condition branch and in a case of false it performs something else as you wrote.

You can write conditional *IF* statements in two ways. The first is single line format which the whole conditional chunk is written in a single line:

```
if n mod 2 then print "Even" else print "Odd"
```

The other way is multiple line statements:

```
input n
if n = 1 then
    print "One"
elseif n = 2 then
    print "Two"
elseif n = 3 then
    print "Three"
else
    print "More than three"
endif
```

It supports nested *IF* in multiple line conditional statements.

Loop structure statements check a loop condition and do the loop body in a case of true until it comes to a false case.

The *FOR TO STEP NEXT* loop statement is deemed as fixed step loop.

See below that prints number one to ten:

```
for i = 1 to 10 step 1
    print i
next i
```

The *STEP* segment is optional if the increment is one. The loop variable after *NEXT* is optional if it is associated with the closest *FOR* segment.

MY-BASIC supports loop on collections by using *FOR IN* statement as well. It's able to iterate a list or a dictionary. The loop variable is assigned with the value of the element which an iterator is currently pointing to. For example:

```
for i in list(1 to 5)
    print i;
next
```

Sometimes, we don't know how many steps a loop would repeat. For this reason, variable step loops are quite essential. There are two kinds of variable loops in MY-BASIC, *WHILE WEND* and *DO UNTIL* loops. See the code below:

```
a = 1
while a <= 10
    print a
wend
```

```
b = 1
do
    print b
until a > 10
```

Just as their names imply, **WHILE WEND** loop do the loop body while the condition is true, and **DO UNTIL** loop do that until the condition is false. A key difference is **WHILE WEND** checks the condition first before executing the loop body, however, **DO UNTIL** checks the condition after the loop body has been executed once.

**EXIT** statement in MY-BASIC is used to interrupt current loop and continue to execute the program after it. It is the same as “break” statement in some other programming languages.

## Use a class

MY-BASIC supports prototype-based programming paradigm which is a kind of OOP (Object-Oriented Programming) paradigm. When we mention “class instance” or “prototype” in MY-BASIC, we mean the same thing. This programming paradigm can also be known as “prototypal”, “prototype-oriented”, “classless”, or “instance-based” programming. Use a pair of **CLASS/ENDCLASS** statements to define a class (a prototype object). Use **VAR** to declare a member variable in a class. It’s able to define member function (aka. Method) in a prototype with the **DEF/ENDDF** statements as well. Write another prototype surrounding with a pair of parentheses after a declaration

statement to inherit from it (use it as a meta class). Use *NEW* to clone a new instance of a prototype.

See below for example to use a class in MY-BASIC:

```
class foo
    var a = 1
    def fun(b)
        return a + b
    enddef
endclass

class bar(foo) ' Use Foo as a meta class (inheriting).
    var a = 2
endclass

inst = new(bar) ' Create a new clone of Bar.
print inst.fun(3);
```

*“bar”* will simply link *“foo”* as a meta class. But *“inst”* will create a new clone of *“bar”* and keep the *“foo”* meta link.

MY-BASIC supports reflection on a class instance with the *REFLECT* statement. It iterates all variable fields and sub routines in a class and its meta class as well, and stores the *name/value* of a variable and the *name/type* of a sub routine to the dictionary *d*. You need to have a binary build with the collection library enabled to use reflection. Let's have a look at an example:

```
class base
  var b = "Base"
  def fun()
    print b;
  enddef
endclass

class derived(base)
  var d = "Derived"
  def fun()
    print d;
  enddef
endclass

i = new(derived)
i.fun();
r = reflect(i)
f = iterator(r)
while move_next(f)
  k = get(f)
  v = r(k)
  print k, ": ", v;
wend

g = get(i, "fun");
g()
```

## Use Lambda

According to Wikipedia's description, a [Lambda](#) abstraction (aka. anonymous function or function literal) is a function definition that is not bound to an identifier. Lambda functions are often:

1. Arguments being passed to higher order functions, or
2. Used for constructing the result of a higher-order function that needs to return a function.

A Lambda becomes a [closure](#) after it captured some values in outer scope.

MY-BASIC has a full support for Lambda, including invocable as a value, higher order function, closure and currying, etc.

A Lambda abstraction begins with a **LAMBDA** keyword.

*' Simple invoke.*

```
f = lambda (x, y) (return x * x + y * y)
print f(3, 4);
```

*' Higher order function.*

```
def foo()
    y = 1
    return lambda (x, z) (return x + y + z)
enddef
l = foo()
print l(2, 3);
```

*' Closure.*

*s = 0*

*def create\_lambda()*

*v = 0*

*return lambda ()*

*(*

*v = v + 1*

*s = s + 1*

*print v;*

*print s;*

*)*

*enddef*

*a = create\_lambda()*

*b = create\_lambda()*

*a()*

*b()*

```
' Currying.  
def divide(x, y)  
    return x / y  
enddef  
def divisor(d)  
    return lambda (x) (return divide(x, d))  
enddef  
half = divisor(2)  
third = divisor(3)  
print half(32); third(32);
```

```
' Return as a value.  
def counter()  
    c = 0  
    return lambda (n)  
    (  
        c = c + n  
        print c;  
    )  
enddef  
acc = counter()  
acc(1)  
acc(2)
```

Lambda enhanced MY-BASIC with functional programming abilities.

## Check the type of a value

You can use **TYPE** statement to tell what the type of a value is, or use a predefined string argument to generate a type information. Eg:

```
print type(123); type("Hi"); ' Get type of values.  
print type("INT"); type("REAL"); ' Get type objects.
```

It's also able to check whether a value match a specific type by using the **IS** operator as follow:

```
print 123 is type("INT"); "Hi" is type("STRING");  
print inst is type("CLASS");
```

You can also use **IS** to tell whether a class instance is inherited from another prototype:

```
print inst is foo;
```

## Import another script file

It's necessary to separate modules to multiple files in large system. MY-BASIC provides an **IMPORT** statement to let a script import another script file. Eg. assuming we got a "a.bas" which is:

```
foo = 1
```

And another "b.bas" which is:

```
import a.bas
```

```
print foo;
```

When MY-BASIC is parsing “b.bas”, it will load “a.bas” as if it was written in “b.bas”.

### Import a module

It's able to put some symbols in a module (or called “namespace” in other programming languages) to avoid naming pollution.

Use **IMPORT** “@xxx” to import a module, and all symbols in that module could be used without the module prefix.

## 3. Core and Standard Libraries

MY-BASIC supplies a set of frequently used function libraries which provides some fundamental numeric and string functions. These function names couldn't be used as a user-defined variable identifier either. For details of these functions, see the figure below:

Type	Name	Description
Numeric	ABS	Returns the absolute value of a number
	SGN	Returns the sign of a number
	SQR	Returns the arithmetic square root of a number
	FLOOR	Returns the greatest integer not greater

		than a number
	CEIL	Returns the least integer not less than a number
	FIX	Returns the integer trimmed format of a number
	ROUND	Returns the specified value to the nearest integer of a number
	SRND	Sets the seed of random number
	RND	Returns a random float number between 0.0 and 1.0
	SIN	Returns the sine of a number
	COS	Returns the cosine of a number
	TAN	Returns the tangent of a number
	ASIN	Returns the arcsine of a number
	ACOS	Returns the arccosine of a number
	ATAN	Returns the arctangent of a number
	EXP	Returns the base-e exponential of a number
	LOG	Returns the base-e logarithm of a number
String	ASC	Returns the integer ASCII code of a character
	CHR	Returns the character of an integer ASCII code
	LEFT	Returns a given number of characters

		from the left of a string
	MID	Returns a given number of characters from a given position of a string
	RIGHT	Returns a given number of characters from the right of a string
	STR	Returns the string type value of a number, or format a class instance with the TOSTRING function
Common	VAL	Returns the number type value of a string, or the value of a dictionary iterator, overridable for referenced usertype and class instance
	LEN	Returns the length of a string or an array, or the element count of a LIST or a DICT, overridable for referenced usertype and class instance
Input & Output	PRINT	Outputs number or string to the standard output stream, user redirectable
	INPUT	Inputs number or string from the standard input stream, user redirectable

Be aware that all those functions besides *PRINT* and *INPUT* require a pair of brackets to surround arguments.

## 4. Collection Libraries

MY-BASIC supplies a set of *LIST*, *DICT* manipulation function libraries which provide creation, accessing, iteration, etc. as below:

Name	Description
LIST	Creates a list
DICT	Creates a dictionary
PUSH	Pushes a value to the tail of a list, overridable for referenced usertype and class instance
POP	Pops a value from the tail of a list, overridable for referenced usertype and class instance
PEEK	Peeks the value of a tail of a list, overridable for referenced usertype and class instance
INSERT	Inserts a value at a specific position of a list, overridable for referenced usertype and class instance
SORT	Sorts a list increasingly, overridable for referenced usertype and class instance
EXIST	Tells whether a list contains a specific value, or whether a dictionary contains a specific key, overridable for referenced usertype and class instance
INDEX_OF	Gets the index of a value in a list, overridable for referenced usertype and class instance

GET	Returns the value of a specific index in a list, or the value of a specific key in a dictionary, or a member of a class instance, overridable for referenced usertype and class instance
SET	Sets the value of a specific index in a list, or the value of a specific key in a dictionary, or a member variable of a class instance, overridable for referenced usertype and class instance
REMOVE	Removes the element of a specific index in a list, or the element of a specific key in a dictionary, overridable for referenced usertype and class instance
CLEAR	Clears a list or a dictionary, overridable for referenced usertype and class instance
CLONE	Clones a collection
TO_ARRAY	Copies all elements from a list to an array
ITERATOR	Gets an iterator of a list or a dictionary
MOVE_NEXT	Moves an iterator to next position for a list or a dictionary

For example:

```
l = list(1, 2, 3, 4)
set(l, 1, "B")
print exist(l, 2); pop(l); peek(l); len(l);

d = dict(1, "One", 2, "Two")
set(d, 3, "Three")
print len(d)
it = iterator(d)
while move_next(it)
    print get(it);
wend
```

MY-BASIC supports accessing an element of a collection using brackets as well:

```
d = dict()
d(1) = 2
print d(1);
```

## 5. Application Programming Interface

There are a few but adequate exposed MY-BASIC APIs (Application Programming Interface) for C, C++, Java, Objective-C, Swift, C#, etc. programmers. MY-BASIC is written with pure C, what you need to do before scripting with MY-BASIC is just copy *my\_basic.h* and

*my\_basic.c* to the target project, then add them to the project build configuration; all interfaces are declared in *my\_basic.h*. Most APIs return an *int* value, they should return *MB\_FUNC\_OK* if there was no execution error most time.

## Interpreter structure

MY-BASIC uses an interpreter structure to store some necessary data structures during parsing and running period; like local, global function directory, variable scope dictionary, abstract syntax tree (list), parsing context, running context, error information, etc. An interpreter structure is a unit of MY-BASIC environment. Invoking between MY-BASIC script and host program also works through this structure.

## Meta information

***unsigned int mb\_ver(void);***

Returns the version number of current interpreter.

***const char\* mb\_ver\_string(void);***

Returns the version number in text of current interpreter.

## Initializing and disposing

***int mb\_init(void);***

This function must and must only be called once before any other operations with MY-BASIC to initialize the entire system.

***int mb\_dispose(void);***

This function must and must only be called once after operations with MY-BASIC to dispose the entire system.

***int mb\_open(struct mb\_interpreter\_t\*\* s);***

This function opens an interpreter structure to get ready for parsing and running.

Common usage of this function does like this:

```
struct mb_interpreter_t* bas = 0;  
mb_open(&bas);
```

***int mb\_close(struct mb\_interpreter\_t\*\* s);***

This function closes an interpreter structure when it is no longer used.

*mb\_open* and *mb\_close* must be matched in pair sequentially.

***int mb\_reset(struct mb\_interpreter\_t\*\* s, bool\_t clr);***

This function resets an interpreter structure to initialization as it was just opened. This function is optional, it will clear all variables, and also all registered global functions if *clr* is *true*.

## Function registration/unregistration

These functions are called to register or remove extended functions.

***int mb\_register\_func(struct mb\_interpreter\_t\* s,  
const char\* n,  
mb\_func\_t f);***

This function registers a function pointer into an interpreter structure using a given name. The function to be registered must be a pointer of *int (\* mb\_func\_t)(struct mb\_interpreter\_t\*, void\*\*)*. A registered

function can be called in MY-BASIC script.

```
int mb_remove_func(struct mb_interpreter_t* s,  
                    const char* n);
```

This function removes a registered function out of an interpreter structure by a given name the same as it was registered.

```
int mb_remove_reserved_func(struct mb_interpreter_t* s,  
                             const char* n);
```

This function removes a reserved function out of an interpreter structure by a given name. Do not use this function unless you really need to.

```
int mb_begin_module(struct mb_interpreter_t* s, const char* n);
```

This function begins a module with a module name. All functions registered after a module began will be put in that module.

```
int mb_end_module(struct mb_interpreter_t* s);
```

This function ends the current module.

## Invoking

These functions are utilities called in extended functions.

```
int mb_attempt_func_begin(struct mb_interpreter_t* s,  
                           void** l);
```

This function checks whether script is invoking an extended function in a legal begin format.

```
int mb_attempt_func_end(struct mb_interpreter_t* s,  
                         void** l);
```

This function checks whether script is invoking an extended function

in a legal end format.

```
int mb_attempt_open_bracket(struct mb_interpreter_t* s,  
                           void** l);
```

This function checks whether script is invoking an extended function in a legal format that begins with an open bracket before arguments list.

```
int mb_attempt_close_bracket(struct mb_interpreter_t* s,  
                             void** l);
```

This function checks whether script is invoking an extended function in a legal format that ends with a close bracket after arguments list.

```
int mb_has_arg(struct mb_interpreter_t* s,  
               void** l);
```

This function detects whether there is any more argument at current execution position in an interpreter structure. Use this function to implement a variable arguments interface function.

```
int mb_pop_int(struct mb_interpreter_t* s,  
               void** l,  
               int_t* val);
```

This function tries to pop an argument of *int\_t* from an interpreter structure.

```
int mb_pop_real(struct mb_interpreter_t* s,  
                void** l,  
                real_t* val);
```

This function tries to pop an argument of *real\_t* from an interpreter structure.

```
int mb_pop_string(struct mb_interpreter_t* s,  
void** l,  
char** val);
```

This function tries to pop an argument of *char\** (String) from an interpreter structure.

```
int mb_pop_usertype(struct mb_interpreter_t* s,  
void** l,  
void** val);
```

This function tries to pop an argument of *void\** (Usertype) from an interpreter structure.

```
int mb_pop_value(struct mb_interpreter_t* s,  
void** l,  
mb_value_t* val);
```

This function tries to pop an argument of *mb\_value\_t* from an interpreter structure. Use this function instead of *mb\_pop\_int*, *mb\_pop\_real* and *mb\_pop\_string* if an extended function accepts arguments of generics types.

```
int mb_push_int(struct mb_interpreter_t* s,  
void** l,  
int_t val);
```

This function pushes an argument of *int\_t* to an interpreter structure.

```
int mb_push_real(struct mb_interpreter_t* s,  
void** l,  
real_t val);
```

This function pushes an argument of *real\_t* to an interpreter

structure.

```
int mb_push_string(struct mb_interpreter_t* s,  
void** l,  
char* val);
```

This function pushes an argument of *char\** (String) to an interpreter structure.

```
int mb_push_usertype(struct mb_interpreter_t* s,  
void** l,  
void* val);
```

This function pushes an argument of *void\** (Usertype) to an interpreter structure.

```
int mb_push_value(struct mb_interpreter_t* s,  
void** l,  
mb_value_t val);
```

This function pushes an argument of *mb\_value\_t* to an interpreter structure. Use this function instead of *mb\_push\_int*, *mb\_push\_real* and *mb\_push\_string* if an extended function returns value of generics types.

## **Class definition**

These functions are used to define a class manually in native side.

```
int mb_begin_class(struct mb_interpreter_t* s,  
void** l,  
const char* n,  
mb_value_t** meta,
```

```
int c,  
mb_value_t* out);
```

This function begins a class definition with a specific name.

```
int mb_end_class(struct mb_interpreter_t* s,  
void** l);
```

This function ends a class definition.

```
int mb_get_class_userdata(struct mb_interpreter_t* s,  
void** l,  
void** d);
```

This function gets the userdata of a class instance.

```
int mb_set_class_userdata(struct mb_interpreter_t* s,  
void** l,  
void* d);
```

This function sets the userdata of a class instance.

## Value manipulation

These functions manipulate values.

```
int mb_get_value_by_name(struct mb_interpreter_t* s,  
void** l,  
const char* n,  
mb_value_t* val);
```

This function gets the value of an identifier with a specific name.

```
int mb_add_var(struct mb_interpreter_t* s,  
void** l,  
const char* n,
```

```
mb_value_t val,  
bool_t force);
```

This function adds a variable with a specific identifier name and a value.

```
int mb_get_var(struct mb_interpreter_t* s,  
void** l,  
void** v);
```

This function gets a token literally, store it in an argument if it's a variable.

```
int mb_get_var_value(struct mb_interpreter_t* s,  
void** l,  
mb_value_t* val);
```

This function gets the value of a variable.

```
int mb_set_var_value(struct mb_interpreter_t* s,  
void** l,  
mb_value_t val);
```

This function sets the value of a variable.

```
int mb_init_array(struct mb_interpreter_t* s,  
void** l,  
mb_data_e t,  
int* d,  
int c,  
void** a);
```

This function initializes an array which MY-BASIC can use. The parameter *mb\_data\_e t* means what's the type of elements in the

array, you can pass *MB\_DT\_REAL* or *MB\_DT\_STRING*; you need to disable the *MB\_SIMPLE\_ARRAY* macro to use a complex array and pass *MB\_DT\_NIL*. The *int\* d* and *int c* stand for ranks of dimensions and dimension count. The function will put a created array to *void\*\* a*.

```
int mb_get_array_len(struct mb_interpreter_t* s,  
void** l,  
void* a,  
int r,  
int* i);
```

This function gets the length of an array. *int r* means which dimension you'd like to get.

```
int mb_get_array_elem(struct mb_interpreter_t* s,  
void** l,  
void* a,  
int* d,  
int c,  
mb_value_t* val);
```

This function gets the value of an element in an array.

```
int mb_set_array_elem(struct mb_interpreter_t* s,  
void** l,  
void* a,  
int* d,  
int c,  
mb_value_t val);
```

This function sets the value of an element in an array.

```
int mb_init_coll(struct mb_interpreter_t* s,  
void** l,  
mb_value_t* coll);
```

This function initializes a collection; you need to pass a valid *mb\_value\_t* pointer with a specific collection type you'd like to initialize.

```
int mb_get_coll(struct mb_interpreter_t* s,  
void** l,  
mb_value_t coll,  
mb_value_t idx,  
mb_value_t* val);
```

This function gets an element in a collection. You can pass *LIST* index or *DICT* key to *mb\_value\_t idx*.

```
int mb_set_coll(struct mb_interpreter_t* s,  
void** l,  
mb_value_t coll,  
mb_value_t idx,  
mb_value_t val);
```

This function sets an element in a collection. You can pass *LIST* index or *DICT* key to *mb\_value\_t idx*.

```
int mb_remove_coll(struct mb_interpreter_t* s,  
void** l,  
mb_value_t coll,  
mb_value_t idx);
```

This function removes an element from a collection. You can pass *LIST* index or *DICT* key to *mb\_value\_t* *idx*.

```
int mb_count_coll(struct mb_interpreter_t* s,  
                  void** l,  
                  mb_value_t coll,  
                  int* c);
```

This function returns the count of elements in a collection.

```
int mb_make_ref_value(struct mb_interpreter_t* s,  
                     void* val,  
                     mb_value_t* out,  
                     mb_dtor_func_t un,  
                     mb_clone_func_t cl,  
                     mb_hash_func_t hs,  
                     mb_cmp_func_t cp,  
                     mb_fmt_func_t ft);
```

This function makes a referenced usertype *mb\_value\_t* object which holds *void\* val* as userdata. Note you need to specify some functors.

```
int mb_get_ref_value(struct mb_interpreter_t* s,  
                    void** l,  
                    mb_value_t val,  
                    void** out);
```

This function gets the raw userdata from a referenced usertype.

```
int mb_ref_value(struct mb_interpreter_t* s,  
                void** l,  
                mb_value_t val);
```

This function increases the reference count of a referenced usertype.

```
int mb_unref_value(struct mb_interpreter_t* s,  
void** l,  
mb_value_t val);
```

This function decreases the reference count of a referenced usertype.

```
int mb_override_value(struct mb_interpreter_t* s,  
void** l,  
mb_value_t val,  
mb_meta_func_u m,  
void* f);
```

This function overrides a meta function of a referenced usertype.

```
int mb_dispose_value(struct mb_interpreter_t* s,  
mb_value_t val);
```

This function disposes a value popped from an interpreter. Now used for strings only.

### **Sub routine manipulation**

```
int mb_get_routine(struct mb_interpreter_t* s,  
void** l,  
const char* n,  
mb_value_t* val);
```

This function gets a sub routine object by its name.

```
int mb_set_routine(struct mb_interpreter_t* s,  
void** l,  
const char* n,
```

```
mb_routine_func_t f,  
bool_t force);
```

This function sets a sub routine with a specific name using a native functor.

```
int mb_eval_routine(struct mb_interpreter_t* s,  
void** l,  
mb_value_t val,  
mb_value_t* args,  
unsigned argc);
```

This function evaluates a subroutine object. *mb\_value\_t\* args* is a pointer of an argument array, *unsigned argc* is the count of arguments.

## Parsing and running

```
int mb_load_string(struct mb_interpreter_t* s,  
const char* l  
bool_t reset);
```

This function loads a string into an interpreter structure; then parses script source to executable structures and appends them to the abstract syntax tree (list).

```
int mb_load_file(struct mb_interpreter_t* s,  
const char* f);
```

This function loads a string into an interpreter structure; then parses script source to executable structures and appends them to the abstract syntax tree (list).

***int mb\_run(struct mb\_interpreter\_t\* s);***

This function runs a parsed abstract syntax tree (list) in an interpreter structure.

***int mb\_suspend(struct mb\_interpreter\_t\* s,  
void\*\* l);***

This function suspends and saves current execution point. Some extended functions need this ability and resume that point after some other operations. Call *mb\_run* again to resume a suspended point.

***int mb\_schedule\_suspend(struct mb\_interpreter\_t\* s,  
int t);***

This function schedules a suspend event, and it will trigger the event after the active statement execution is done. It's useful to do so when you need to do something else during the whole execution.

A). *mb\_schedule\_suspend(s, MB\_FUNC\_SUSPEND);* It's re-enterable which means next *mb\_run* will resume execution from where you suspended. B). *mb\_schedule\_suspend(s, MB\_FUNC\_END);* Terminate an execution normally, no error message. C). *mb\_schedule\_suspend(s, MB\_EXTENDED\_ABORT);* Or pass an argument greater than *MB\_EXTENDED\_ABORT* to terminate an execution and trigger an error message. You can call *mb\_schedule\_suspend* either in *\_on\_stepped* or in a scripting interface function. The difference between *mb\_schedule\_suspend* and *mb\_suspend* is that *mb\_suspend* can be called in a scripting interface only, and it cannot trap type B) and C) suspension.

## Debugging

```
int mb_debug_get(struct mb_interpreter_t* s,  
                 const char* n,  
                 mb_value_t* val);
```

This function retrieves the value of a variable using the identifier in an interpreter structure.

```
int mb_debug_set(struct mb_interpreter_t* s,  
                 const char* n,  
                 mb_value_t val);
```

This function sets a variable using the identifier with a given value in an interpreter structure.

```
int mb_debug_get_stack_trace(struct mb_interpreter_t* s,  
                             void** l,  
                             char** fs,  
                             unsigned fc);
```

This function gets current stack frame trace. It requires the *MB\_ENABLE\_STACK\_TRACE* macro enabled to use this function.

```
int mb_debug_set_stepped_handler(struct mb_interpreter_t* s,  
                                 mb_debug_stepped h);
```

This function sets a single step handler of an interpreter structure. The function to be set must be a pointer of *void (\* mb\_debug\_stepped\_handler\_t)(struct mb\_interpreter\_t\*, void\*\*, char\*, int, unsigned short, unsigned short)*. This function is useful for step by step debugging.

## Type handling

```
const char* mb_get_type_string(mb_data_e t);
```

This function returns type information in string of a given type.

## Error handling

```
int mb_raise_error(struct mb_interpreter_t* s,  
                  void** l,  
                  mb_error_e err,  
                  int ret);
```

This function raises an error manually.

```
mb_error_e mb_get_last_error(struct mb_interpreter_t* s);
```

This function returns the latest error information of an interpreter structure.

```
const char* mb_get_error_desc(mb_error_e err);
```

This function returns the description string of error information.

```
int mb_set_error_handler(struct mb_interpreter_t* s,  
                        mb_error_handler_t h);
```

This function sets an error callback handler of an interpreter structure.

## Stream redirection

```
int mb_set_printer(struct mb_interpreter_t* s,  
                  mb_print_func_t p);
```

This function sets a *PRINT* handler of an interpreter structure. Use

this to customize an output handler for the *PRINT* statement. The function to be set must be a pointer of *int (\* mb\_print\_func\_t)(const char\*, ...)*. *printf* is set by default.

```
int mb_set_inputter(struct mb_interpreter_t* s,  
                    mb_input_func_t p);
```

This function sets the *INPUT* handler of an interpreter structure. Use this to customize an input handler for the *INPUT* statement. The function to be set must be a pointer of *int (\* mb\_input\_func\_t)(char\*, int)*. *mb\_gets* is set by default.

## Miscellaneous

```
int mb_gc(struct mb_interpreter_t* s,  
           int_t* collected);
```

This function tries to trigger a garbage collection.

```
int mb_get_userdata(struct mb_interpreter_t* s,  
                    void** d);
```

This function gets the userdata of an interpreter instance.

```
int mb_set_userdata(struct mb_interpreter_t* s,  
                    void* d);
```

This function sets the userdata of an interpreter instance.

```
int mb_set_import_handler(struct mb_interpreter_t* s,  
                           mb_import_handler_t h);
```

This function sets a customized module importing handler.

```
int mb_gets(char* buf,  
            int s);
```

A more safety evolvement of the standard *gets*.

```
char* mb_memdup(const char* val,  
                unsigned size);
```

This function duplicates a piece of memory to a MY-BASIC manageable buffer structure; use this to generate an argument for strings to be pushed. Note this function only copy bytes in given *size*, thus you have to add an extra byte to *size* for ending “\0”.

```
int mb_set_memory_manager(mb_memory_allocate_func_t a,  
                          mb_memory_free_func_t f);
```

This function sets a memory allocator and a freer globally to MY-BASIC.

## 6. Scripting with MY-BASIC

As to source code portability, the C programming language is most outstanding, because C compilers are available on almost every platform; that is why MY-BASIC is written in pure clean C so it can be compiled for PC, Tablet, Pad, Mobile Phone, PDA, Video Game Console, Raspberry Pi, Intel Edison, Arduino and even MCU, with none or few porting modifications. It would be pretty easy to bind MY-BASIC in an existing project by just adding the MY-BASIC core which consists of a header declaration file and corresponding C implementation file into the target project.

First of all, you should recognize which parts in your project require execution speed and low level control, and which parts require

flexibility and augmentability. It's not wise to code kernel computation-intensive modules in script; script is appropriate for volatile parts of an entire program. There is no one fits all solution; scripting programming languages are not omnipotent.

If it is explicit to you that using a scripting language would benefit your project then you should make and expose some interfaces correctly. More details on how to create your own scripting interfaces will be dealt with in the next chapter. After that you may complete your program with MY-BASIC script, invoking those scripting interfaces and pack them together into a publishable version.

Besides the scripting benefits, play with a scripting language itself is a really enjoyable thing.

## 7. Customizing MY-BASIC

### Redirect PRINT and INPUT

Include a header file to use variable argument list:

```
#include <stdarg.h>
```

Customizable print handler:

```
int my_print(const char* fmt, ...) {  
    char buf[1024];  
    va_list argptr;  
  
    va_start(argptr, fmt);  
    vsnprintf(buf, sizeof(buf), fmt, argptr);  
    va_end(argptr);  
  
    printf(buf); /* Change me. */  
  
    return MB_FUNC_OK;  
}
```

Customizable input handler:

```

int my_input(char* buf, int s) {
    int result = 0;
    if(fgets(buf, s, stdin) == 0) { /* Change me. */
        fprintf(stderr, "Error reading.\n");
        exit(1);
    }
    result = (int)strlen(buf);
    if(buf[result - 1] == '\n')
        buf[result - 1] = '\0';

    return result;
}

```

Register handlers to an interpreter:

```

mb_set_printer(bas, my_print);
mb_set_inputter(bas, my_input);

```

Now your printer and inputter would be invoked.

## Write scripting APIs

MY-BASIC is free and open source software released under the MIT license which allows you to use, modify, extend and distribute the software for either commercial or noncommercial uses. You might need more scripting libraries according to your specific requirement though MY-BASIC has already provided some functions. It is really

simple in MY-BASIC to do so.

The first step is to define the function in your host program. All native callee functions that will be invoked from MY-BASIC script is a pointer of type *int (\* mb\_func\_t)(struct mb\_interpreter\_t\*, void\*\*)*. Since an interpreter structure is used as the first argument of an extended function, the function actually can pop any number of arguments from the interpreter structure and push none or one return value back into the structure. The *int* return value indicates an execution status of an extended function which always returns *MB\_FUNC\_OK* for no error. Let's make a *maximum* function that returns the maximum value of two integers as a tutorial; see code below:

```

int maximum(struct mb_interpreter_t* s, void** l) {
    int result = MB_FUNC_OK;
    int m = 0;
    int n = 0;
    int r = 0;

    mb_assert(s && l);

    mb_check(mb_attempt_open_bracket(s, l));
    mb_check(mb_pop_int(s, l, &m));
    mb_check(mb_pop_int(s, l, &n));
    mb_check(mb_attempt_close_bracket(s, l));

    r = m > n ? m : n;
    mb_check(mb_push_int(s, l, r));

    return result;
}

```

Quite simple, isn't it.

The second step is to register defined functions like: *mb\_reg\_fun(bas, maximum)* (assuming we already have *struct mb\_interpreter\_t\* bas* defined).

After that you can use a registered function as any other scripting interfaces in MY-BASIC like:

```
i = maximum(1, 2)  
print i
```

To perform a user defined abort, just return an integer value greater equal than a macro *MB\_EXTENDED\_ABORT*. It is recommended to add an abort value like:

```
typedef enum mb_user_abort_e {  
    MB_ABORT_FOO = MB_EXTENDED_ABORT + 1,  
    /* more... */  
};
```

Then write *return MB\_ABORT\_FOO;* in your customized function when something uncontrollable happened.

## Use usertype values

MY-BASIC build-in types maybe not enough for all purposes. It's easy to use Ustertype in MY-BASIC. It can accept whatever type you give it. MY-BASIC doesn't care what a Ustertype is; it just holds a Ustertype value at a variable or an array element. Note *MB\_SIMPLE\_ARRAY* macro must be disabled when you wish to store Ustertype in arrays. There are only two essential interfaces to get or set a Ustertype: *mb\_pop\_ustertype* and *mb\_push\_ustertype*. You can push a *void\** to an interpreter and pop a value as *void\** as well. This is more flexible than using only build-in types.

## Macros

Some features of MY-BASIC could be customized with macros.

### ***MB\_SIMPLE\_ARRAY***

Enabled by default. An entire array uses a unified type mark, which means there are only two kinds of array: *string* and *real\_t*.

Disable this macro if you would like to store generic type values in an array including *int\_t*, *real\_t*, *usertype*. Besides, array of *string* is still another kind. Note non simple array requires extra memory to store type mark of each element.

### ***MB\_ENABLE\_ARRAY\_REF***

Enabled by default. Compiles with referenced array if this macro defined, otherwise compiles as value type array.

### ***MB\_MAX\_DIMENSION\_COUNT***

Defined as 4 by default. Change this to support arrays of bigger maximum dimensions.

### ***MB\_ENABLE\_COLLECTION\_LIB***

Enabled by default. Compiles including *LIST* and *DICT* libraries if this macro is defined.

### ***MB\_ENABLE\_USERTYPE\_REF***

Enabled by default. Compiles with referenced usertype support if this macro defined.

### ***MB\_ENABLE\_CLASS***

Enabled by default. Compiles with class (prototype) support if this macro defined.

### ***MB\_ENABLE\_LAMBDA***

Enabled by default. Compiles with Lambda (anonymous function) support if this macro defined.

### ***MB\_ENABLE\_MODULE***

Enabled by default. Compiles with module (namespace) support if this macro defined. Use *IMPORT "@xxx"* to import a module, and all symbols in that module could be used without the module prefix.

### ***MB\_ENABLE\_UNICODE***

Enabled by default. Compiles with UTF8 manipulation ability if this macro defined, to handle UTF8 string properly with functions such as *LEN*, *LEFT*, *RIGHT*, *MID*, etc.

### ***MB\_ENABLE\_UNICODE\_ID***

Enabled by default. Compiles with UTF8 token support if this macro defined, this feature requires *MB\_ENABLE\_UNICODE* enabled.

### ***MB\_GC\_GARBAGE\_THRESHOLD***

Defined as 16 by default. It will trigger a sweep-collect GC cycle when such number of deallocation occurred.

### ***MB\_ENABLE\_ALLOC\_STAT***

Enabled by default. Use *MEM* to tell how much memory in bytes is allocated by MY-BASIC. Note statistics of each allocation takes *sizeof(intptr\_t)* more bytes memory.

### ***MB\_ENABLE\_SOURCE\_TRACE***

Enabled by default. MY-BASIC can tell where it goes in source code when an error occurs.

Disable this to reduce some memory occupation. Only do this on

memory sensitive platforms.

### ***MB\_ENABLE\_STACK\_TRACE***

Enabled by default. MY-BASIC will record stack frames including sub routines and native functions if this macro defined.

### ***MB\_CONVERT\_TO\_INT\_LEVEL***

Describes how to deal with Real numbers after an expression is evaluated. Just leave it a Real if it's defined as *MB\_CONVERT\_TO\_INT\_LEVEL\_NONE*; otherwise try to convert it to an Integer if it doesn't contains decimal part if it's defined as *MB\_CONVERT\_TO\_INT\_LEVEL\_ALL*. Also you could use the *mb\_convert\_to\_int\_if\_possible* macro to deal with an *mb\_value\_t* in your own scripting interface functions.

### ***MB\_COMPACT\_MODE***

Enabled by default. C *struct* may use a compact layout.

This might cause some strange pointer accessing bugs with some compilers (eg. Some embedded system compilers). Try disabling this if you met any strange bugs.

### ***\_WARNING\_AS\_ERROR***

Defined as 0 by default.

Define this macro as 1 in *my\_basic.c* to treat warnings as error, or they will be ignored silently.

Something like divide by zero, wrong typed arguments passed will trigger warnings.

### ***\_HT\_ARRAY\_SIZE\_DEFAULT***

Defined as 193 by default. Change this in *my\_basic.c* to resize the

hash tables. Smaller value will reduce some memory occupation, size of hash table will influence tokenization and parsing time during **loading**, won't influence **running** performance most of the time (except cross scope identifier lookup).

### ***\_SINGLE\_SYMBOL\_MAX\_LENGTH***

Defined as 128 by default. Max length of a lexical symbol.

## **8. Memory Occupation**

In some memory limited environments, memory occupation is often a sensitive bottleneck. MY-BASIC provides a method to count how much memory has an interpreter context allocated. Write script like below to tell how much memory in bytes does MY-BASIC allocated:

```
print mem ' The keyword MEM is right for this
```

Note that it will take *sizeof(intptr\_t)* bytes more of each allocation if this statistics is enabled.

Comment the *MB\_ENABLE\_SOURCE\_TRACE* macro in *my\_basic.h* to disable source trace to reduce some memory occupation, but you will lose the error locating feature as well.

Redefine the *\_HT\_ARRAY\_SIZE\_DEFAULT* macro with a smaller value minimum to *1* in *my\_basic.c* to reduce memory occupied by hash tables in MY-BASIC. Value *1* means a linear lookup.

The memory is limited in embedded systems which can run for years and cause a severe waste of memory due to fragmentation. Besides,

it's efficient for MY-BASIC to customizing a memory allocator, even on systems with a plenty of memory. MY-BASIC provides an interface that let you do so.

An allocator need to be in form of:

```
typedef char* (* mb_memory_allocate_func_t)(unsigned s);
```

And a freer:

```
typedef void (* mb_memory_free_func_t)(char* p);
```

Then you can tell MY-BASIC to use them globally instead of standard *malloc* and *free* by:

```
MBAPI int mb_set_memory_manager(mb_memory_allocate_func_t a,  
mb_memory_free_func_t f);
```

Note the functors only affect things going inside *my\_basic.c*, but *main.c* still uses the standard pair.

There is already a simple memory pool implementation in *main.c*. You need to make sure the *\_USE\_MEM\_POOL* macro is defined to enable this pool, and undefine it to disable the mechanism.

There are four functions in this implementation as a tutorial: *\_open\_mem\_pool* opens the pool when setting up an interpreter; *\_close\_mem\_pool* closes the pool when terminating; a pair of *\_pop\_mem* and *\_push\_mem* will be registered to MY-BASIC. Note *\_pop\_mem* will call the standard *malloc* if an expected size is not a common size in MY-BASIC; and it will take *sizeof(union \_pool\_tag\_t)* extra bytes to store meta data with each common size allocation. A typical workflow may looks like below:

```
_open_mem_pool(); // Open it.  
mb_set_memory_manager(_pop_mem, _push_mem); // Register  
them.  
{  
    mb_init();  
    mb_open(&bas);  
    // Other deals with MY-BASIC.  
    mb_close(&bas);  
    mb_dispose();  
}  
_close_mem_pool(); // Finished.
```

Strictly speaking, the tutorial pool doesn't guarantee to allocate continuous address memory, it is an object pool other than a memory pool, which pops a free chunk of memory with an expected size to user, and pushes it to the stack back when user frees it instead of freeing it to system. This could be a good start if you would like to implement your own memory pool algorithm optimized for a specific system.

## 9. Using MY-BASIC as a Standalone Interpreter

You would be familiar with the MY-BASIC interpreter if you have tried the hello world tutorial. There are some useful commands for the interactive interpreter mode:

Command	Summary	Usage
HELP	Shows help information.	
CLS	Clears screen.	
NEW	Clears current program.	
RUN	Runs current program.	
BYE	Quits interpreter.	
LIST	Lists current program.	LIST [l [n]], l is start line number, n is line count.
EDIT	Edits (modify/insert/remove) a line in current program.	EDIT n, n is line number. EDIT -i n, insert a line before a given line, n is line number. EDIT -r n, remove a line, n is line number.
LOAD	Loads a file as current program.	LOAD *.*.
SAVE	Saves current program to a file.	SAVE *.*.
KILL	Deletes a file.	KILL *.*.
DIR	List a directory.	DIR p, p is a directory path.

Type a command (maybe also with several arguments) and hit enter to execute it. Command is only an aspect of the interpreter other than keyword, that is to say it is valid to use them as variable identifiers in a program; but to avoid reading confusion and conflict,

and anyway, you may consider different identifier naming.

Pass a file path to the binary to load and run that script file in file execution mode.

Pass an argument `-e` and an expression to evaluate and print it, eg. `-e "2 * (3 + 4)"`, note the double quotation marks are required when an expression contains space characters.

Pass an option `-p` and a number to set the memory pool threshold size of an interpreter, eg. `-e 33554432` to set the threshold to 32MB. MY-BASIC will tidy the memory pool when the free list reached this size.
